

Population.java

Objective: To implement different sorting methods and organize a large set of data.

Background:

We have a list of over 30,000 USA cities and their populations. It would be helpful if the data could be sorted in different and helpful ways to answer important questions. Some sample queries: “What are the most populous cities in USA?” or “What are the most populous cities in a chosen state?” or “What states in the USA have a city named Springfield?”

In this project, you will create a database from the list of USA cities and sort the data. You will sort the data for population and city name using Selection Sort, Insertion Sort, and Merge Sort.

Assignment:

Download the file **Population.zip** from Mr Greenstein’s web site. Unzip the file and it will create a **Population** directory containing three files: a starter **City.java** file, a starter **Population.java** file, and the city data file **usPopData2017.txt**. Do all of your work in the **Population** directory. You will need the **FileUtils** and **Prompt** classes for this project.

1. Enhance the **City** class to hold one city’s data. It should implement **Comparable<City>** and have **private** fields to hold the city name (**String**), the state name (**String**), city type (**String**), and the population (**int**). It should also have a constructor, and **compareTo()** and **equals()** methods. The **toString()** method is already provided. The **compareTo()** method will sort **City** populations. Use the following algorithm for **compareTo()**:
 - a. if populations are different, return **this.population - other.population**.
 - b. Else if state names are different, return **this.state compareTo other.state**.
 - c. Else return **this.name compareTo other.name**.
2. Write a method to read the **usPopData2017.txt** file and load the **List<City> cities** with data. Use **FileUtils openToRead** method and the delimiter “[\t\n]” (delimiting tabs and newlines, see **Scanner** API for **useDelimiter** method).
3. Modify your **SortMethods** class to handle **City** objects. Change each **Integer[]** to **List<City>**; change each **arr[x]** to **arr.get(x)**; change each **new Integer[y]** to **new ArrayList<City>()**.
4. Create sorts for the following orderings.
 - a. Cities in ascending population order (Selection Sort)
 - b. Cities in descending population order (Merge Sort)
 - c. Cities in ascending name order (Insertion Sort)
 - d. Cities in descending name order (Merge Sort)
5. Add code to measure the time taken for the sort.

```
long startMillisec = System.currentTimeMillis();
<sort here>
long endMillisec = System.currentTimeMillis();
```

6. Create methods to handle two more queries. Use any sort method.
 - a. Most populous cities in a chosen state.
 - b. List all cities in the USA of a chosen city name.
7. Use the sample run below as a model to format your output. The “Enter selection” prompt should forgive mistyped entries. Entering city and state names should be case-sensitive (should match case exactly). Algorithm elapsed time will change depending on processor speed and operating system conditions. In general, Selection Sort is noticeably the slowest, and Insertion Sort should take about half that time. Merge Sort should take significantly less time than the other sorts.

	State	City	Type	Population
1:	Illinois	Balance of Niles	township	0
2:	Illinois	Balance of Stites	township	0
3:	Illinois	Balance of West Peoria	township	0
4:	Indiana	Balance of Pigeon	township	0
5:	New Hampshire	Kilkenny	township	0
6:	New Hampshire	Livermore	town	0
